Mathematical Programming

Lecture 03

2021.09.09

Electrical & Computer ENGINEERING

TEPPER

USRA Universities Space Research Association

Agenda

- Constrained Optimization Models

- Linear Programming

  - Simplex and Interior Point methods

  - Duality brief overview

- (Mixed-)Integer Programming

  - Branch and bound and cutting planes

- (Mixed-)Integer Nonlinear Programming

- Nonlinearity

- Intro to Complexity

Constrained Optimization Models

- Exploration of real-world, looking for optimal solution can be time-consuming, expensive and prone to errors
- Instead, we would like to have a model of the real-world
  - Represent our understanding of the real world
  - Incorporate assumptions and simplifications
  - Tradeoff between tractable and valid
- A useful paradigm is Mathematical Programming, where we write in mathematical equations
  - Objective(s)
  - Constraint(s)
    - All with respect to certain variables

$$\min_{\mathbf{x}} f(x)$$
$$\text{s.t. } g(x) \leq 0$$

Electrical & Computer ENGINEERING

TEPPER

USRA Universities Space Research Association

3

Operations Research approach

- Define the problem
- Formulate the model
  - Requirements
  - Simplifications
  - Assumptions
- Solve / Analyze the model
- Interpret the results

- All steps are vital to provide a solution!

$$\min_{x} f(x)$$
$$\text{s.t. } g(x) \leq 0$$

Simple example

Let's propose a production plan that increases the profit of a company!

… we need more data than that.

The company only produces a finite set of products and each has its price. Besides, there are some production limitations.

To propose a model of this situation we need to identify certain key aspects of the problem.
- What are relevant parameters or data?
- Which decisions can we make? What is unknown? What is controllable?
- What limitations are relevant? What determines how a solution is valid (feasibility)?
- What is our goal?

Once those are clear, we can propose a model.

Simple example

After addressing those questions we reach the following problem statement.

Suppose there is a company that produces two different product, A and B, which can be sold at different values, $5.5 and $2.1 per unit, respectively.

The company only counts with a single machine with electricity usage of at most 17kW/day; and producing each A and B consumes 8kW/day and 2kW/day, respectively.

Besides, the company can only produce at most 2 more units of A than B per day.

This is a valid model, but it would be easier to solve if we had a mathematical representation.

Assuming the units produced of A are x_1 and of B are x_2 we have

$$\max \quad 5.5x_1 + 2.1x_2$$
$$-x_1 + x_2 \leq 2$$
$$8x_1 + 2x_2 \leq 17$$
$$x_1, x_2 \geq 0$$

Linear Programming

A simplification of the general model presented before assumes that all the constraints and objective are linear, and the variables are continuous

$$\min_{\mathbf{x}} \mathbf{c}^{\top} \mathbf{x}$$
$$s.t. \, \mathbf{A}\mathbf{x} \leq \mathbf{b}$$

The feasible region of a Linear Program (LP) is a convex polyhedron

$$
\begin{aligned}
\max \quad & 5.5x_1 + 2.1x_2 \\
& -x_1 + \quad x_2 \leq 2 \\
& 8x_1 + \quad 2x_2 \leq 17 \\
& x_1, \, x_2 \geq 0
\end{aligned}
$$

Interior-point methods
- Path through interior of polytope
- Polynomial time

Simplex methods
- Vertex hopping
- (Worst-case) Exponential time

Most solvers use simplex!
- 1e7 variables is tractable!

[1] Adapted from Integer Programming (1st ed. 2014) by Michele Conforti, Gérard Cornuéjols, and Giacomo Zambelli

Simplex (overview)

$$\min_{\mathbf{x}} \mathbf{c}^\top \mathbf{x}$$
$$s.t. \ \mathbf{Ax} = \mathbf{b}$$
$$\mathbf{x} \geq 0$$
$$\mathbf{x} \in \mathbb{R}^n$$

$$\begin{bmatrix} 1 & -\mathbf{c}^\top & 0 \\ 0 & \mathbf{A} & \mathbf{b} \end{bmatrix}$$

$$\begin{bmatrix} 1 & -\mathbf{c}_B^\top & -\mathbf{c}_N^\top & 0 \\ 0 & \mathbf{I} & \mathbf{D} & \mathbf{b} \end{bmatrix}$$

1. Write the "simplex tableau"
2. Convert to canonical form (select basis)
3. "Price out" basic variables
4. If solution can be improved, we pivot (swap basic and non-basic variables)

Can efficiently restart from any feasible solution

$$\begin{bmatrix} 1 & 0 & -\bar{\mathbf{c}}_N^\top & z_B \\ 0 & \mathbf{I} & \mathbf{D} & \mathbf{b} \end{bmatrix}$$

Relative costs

Objective value

Basic variables values

Basic variables

Non-basic variables (assumed=0)

Linear Programming

Modeling and Simplex method

Let's jump to the code!
https://colab.research.google.com/github/bernalde/QuIPML/blob/main/notebooks/Notebook%201%20-%20LP%20and%20IP.ipynb

Interior-point (brief overview)

- More details to it but the basics
- Intuition: starting from a feasible point, we approach the edges by having a monotonic barrier when close.
- Synonyms: Barrier method
- Not very efficient at restart
- **Very** useful when problems are **dual degenerate**

- **What is duality?**

[1] Adapted from Integer Programming (1st ed. 2014) by Michele Conforti, Gérard Cornuéjols, and Giacomo Zambelli
[2] https://en.wikipedia.org/wiki/Karmarkar%27s_algorithm

Linear Programming

Interior point method

Back to the code!
https://colab.research.google.com/github/bernalde/QuIPML/blob/main/notebooks/Notebook%201%20-%20LP%20and%20IP.ipynb

Duality (very brief overview)

$$\min_{\mathbf{x}} \mathbf{c}^\top \mathbf{x}$$
$$s.t.\ \mathbf{A}\mathbf{x} = \mathbf{b}$$
$$\mathbf{x} \geq 0$$
$$\mathbf{x} \in \mathbb{R}^n$$

The Lagrangian function $\mathcal{L}(\lambda)$ (with deep meaning in classical mechanics and the least energy principle) defines a lower bound on our optimization problem, so we maximize it

$$\max_{\lambda} \mathcal{L}(\lambda) = \max_{\lambda} \lambda^\top \mathbf{b}$$
$$s.t.\ \lambda^\top \mathbf{A} \leq \mathbf{c}^\top$$

$$\min_{\mathbf{x}} \mathbf{c}^\top \mathbf{x} + \lambda^\top (\mathbf{b} - \mathbf{A}\mathbf{x})$$
$$s.t.\ \mathbf{x} \geq 0$$

Lagrangian or dual multipliers

$$\mathcal{L}(\lambda) = \min_{\mathbf{x} \geq 0} \mathbf{c}^\top \mathbf{x} + \lambda^\top (\mathbf{b} - \mathbf{A}\mathbf{x})$$
$$= \lambda^\top \mathbf{b} + \min_{\mathbf{x} \geq 0} (\mathbf{c}^\top - \lambda^\top \mathbf{A})\mathbf{x}$$
$$= \lambda^\top \mathbf{b} + \begin{cases} 0, & \text{if } \mathbf{c}^\top - \lambda^\top \mathbf{A} \geq \mathbf{0}^\top \\ -\infty, & \text{otherwise} \end{cases}$$

For LPs (and in general convex problems) the following holds:

Strong duality: $\lambda^{*\top} \mathbf{b} = \mathbf{c}^\top \mathbf{x}^*$

LP – State of the art

Previous results with 45 problems with ~205k constraints, ~225k variables and ~2.5M nonzeros.

The usual density of LP problems (in this case ~0.005% in average) is **very** low!

Best performing solvers used to be IBM CPLEX, FICO XPRESS and GUROBI

- They are not included in the benchmarks because of an incident in 2018
- but now, new players are in the arena! 🇨🇳

[1] http://plato.asu.edu/talks/euro2019.pdf
[2] https://mattmilten.github.io/mittelmann-plots/
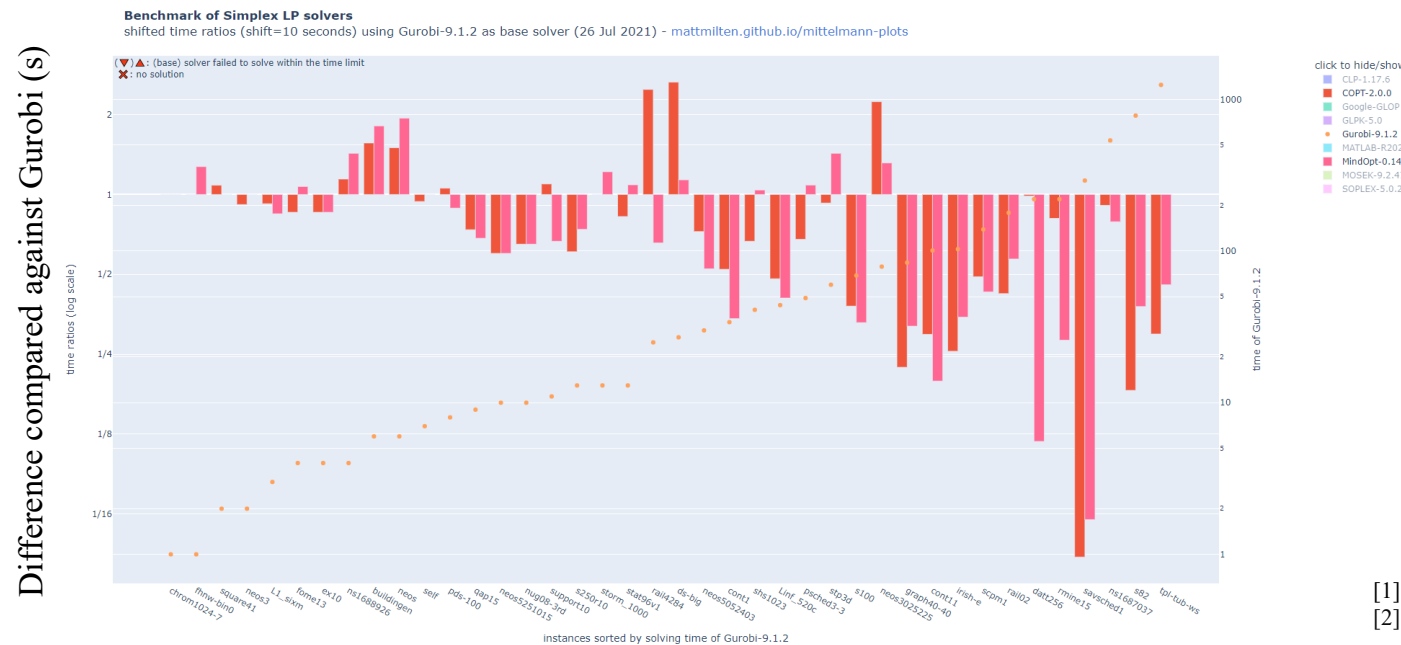

Simple example - Continued

We found that the optimal solution was to produce 3.3 units of B, 1.3 units of A, and that would yield a profit of \$14.08.

But what if we can only produce an integer number of products?
We modify our formulation to include this new information.

$$
\begin{aligned}
\max \quad & 5.5x_1 + 2.1x_2 \\
& -x_1 + x_2 \leq 2 \\
& 8x_1 + 2x_2 \leq 17 \\
& x_1, x_2 \geq 0 \\
& x_1, x_2 \text{ integer}
\end{aligned}
$$

The feasible region is no longer convex!
[1] Adapted from Integer Programming (1st ed. 2014) by Michele Conforti, Gérard Cornuéjols, and Giacomo Zambelli

15

Modeling non-convexities

The real-world is often abrupt, unexpected, sudden, discontinuous, non-smooth, …
This is the point where (Mixed-)Integer Programming comes into play!

$$\min_{\mathbf{x}} f(x)$$
$$\text{s.t. } g(x) \leq 0$$
some or all x_i are integer

Integer Programming can be understood as the universal tool for modeling non-convexities and discontinuities
- Integrality condition may arise from indivisibility (people, objects)
- But it also can be used as a "trigger" or "switch"
  - Logical conditions such as disjunctions, implications, precedence can be modeled using this tool
- This is applicable to all areas of decision-making
  - ubiquitous, omnipresent [1]

[1] Adapted from Egon Balas' lecture on Integer Programming

16

Enumerating

How hard can it be just to look at all the possible values, checking if they satisfy the constraints (being feasible) and comparing their objective function?

- Assuming only binary variables, the number of solutions grows as 2^n
- Many problems actually deal with permutations (assignments) therefore the number of solutions grow as $n!$
[1] Integer Programming (1st ed. 2014) by Michele Conforti, Gérard Cornuéjols, and Giacomo Zambelli

(Mixed-)Integer Programming

Solution and Enumeration

Back to the code!
https://colab.research.google.com/github/bernalde/QuIPML/blob/main/notebooks/Notebook%201%20-%20LP%20and%20IP.ipynb

(Mixed-)Integer Programming

A Mixed-Integer Program (MIP) is an optimization problem of the form

$$\min_{\mathbf{x}} f(x)$$
$$\text{s.t. } g(x) \leq 0$$
$$\text{some or all } x_i \text{ are integer}$$

Main concern is that is a strongly NP-complete problem
Branch-and-bound
- Solution of each search node using linear programming

Cutting plane methods
- Polyhedral theory

Enhanced with constraint programming methods
- Logic inference
- Domain reduction

Feasible solutions of the integer program are the crosses

Add the Right Constraints

$P_{initial}$ → P_{final}

Branch-and-Bound

Each node in branch-and-bound is a new MIP

(Mixed-)Integer Programming

$$\begin{aligned}
\max \quad & 5.5x_1 + 2.1x_2 \\
& -x_1 + x_2 \le 2 \\
& 8x_1 + 2x_2 \le 17 \\
& x_1, x_2 \ge 0 \\
& x_1, x_2 \text{ integer}
\end{aligned}$$

Branch-and-bound
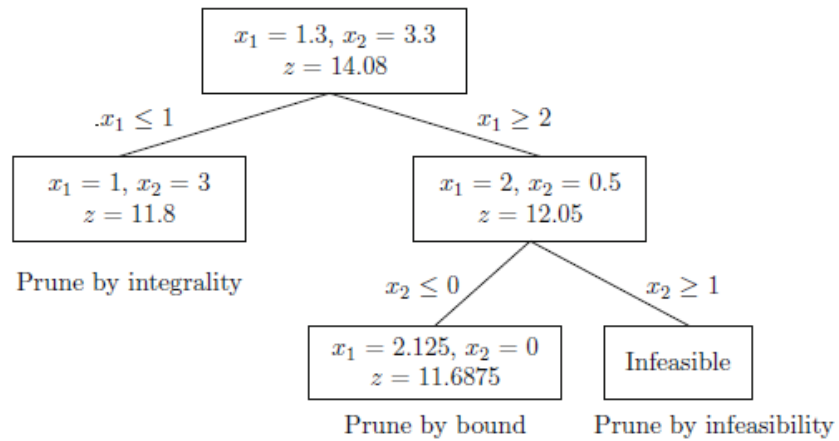

Cutting-plane methods

[1] Integer Programming (1st ed. 2014) by Michele Conforti, Gérard Cornuéjols, and Giacomo Zambelli

(Mixed-)Integer Programming

- Speedup between CPLEX 1.2 (1991) and CPLEX 11 (2007): 29,000 times

- Gurobi 1.0 (2009) comparable to CPLEX 11

- Speedup between Gurobi 1.0 and Gurobi 8.0 (2018): 91 times

- Total speedup 1991-2018: 2'600,000 times

- A MIP that would have taken 30 days to solve 27 years ago can now be solved in the same 25-year-old computer in less than one second

- Hardware speed: 122.3 Pflops/s in 2018 vs. 59.7 Gflops/s in 1993 2'000,000 times

- Total speedup: **5.4 trillion times!**

- A MIP that would have taken 171,000 years to solve 27 years ago can now be solved in a modern computer in less than one second
[1] https://www.ferc.gov/CalendarFiles/20100609110044-Bixby,%20Gurobi%20Optimization.pdf

# Modeling the real-world

The real-world is apart of abrupt, **nonlinear!**

$$\min_{\mathbf{x}} f(x)$$
$$\text{s. t. } g(x) \leq 0$$
$$\text{some or all } x_i \text{ are integer}$$

Although we can model discontinuities with integer variables, we can summarize more information using nonlinear constraints and objectives

- Assumption that $f(\mathbf{x}) = \mathbf{c}^\top \mathbf{x}, g(\mathbf{x}) = \mathbf{A}\mathbf{x} - \mathbf{b}$ does not hold in general
- This only makes our problem harder

Flat Earth | Reality

(Mixed-)Integer Nonlinear Programming

So far, we have only discussed linear constraints and objective(s), but nonlinearity is key to modeling.
Representation of Turing Machine[1]

"*Most industrial processes* can be formulated as MINLP. Its expressive power is remarkable: it can encode any Turing Machine, including universal ones, such as Minsky's Recording Machine, which means that **every problem** can be formulated as a MINLP*."

- L. Liberti, Mathematical Programming. 2017

MINLP is **NP-Hard** since:

$$SAT \rightarrow BIP \subset ILP \subset MILP \subset MINLP$$

- Theorem 3 in Liberti, L. and Martinelli, F. "Mathematical programming: Turing completeness and applications to software analysis". 2014
- Problem 2, main Theorem in Karp, R.M. "Reducibility Among Combinatorial Problems". 1972

[1] COSC 545 - Theory of Computation, Georgetown University. Retrieved from http://people.cs.georgetown.edu/~cnewport/teaching/cosc545-spring14/ on 02/17/2019.

# Convex (M)INLP State of the art

Complexity boundary does not lie between linearity and nonlinearity

But between convexity and non-convexity.

Convex (M)INLP problems are more challenging but manageable

Benchmark from 335 problems with ~1000 variables and constraints in average

Branch-and-bound methods

(M)ILP based methods

[1] Kronqvist, J., Bernal, D. E., Lundell, A. and Grossmann, I. E. [2018], `A review and comparison of solvers for convex MINLP', Optimization and Engineering pp. 1-59.

Simple example – Final version

We found that the optimal solution of the convex INLP was to produce 1 unit of A, and 2 units of B, and that would yield a profit of $9.7.

Finally, we include an extra constraint, where the production of B minus 1, squared, can only be greater than 1/2 plus the production of A

$$\max_{x_1, x_2} 5.5x_1 + 2.1x_2$$
$$s.t.\ x_2 \leq x_1 + 2$$
$$8x_1 + 2x_2 \leq 17$$
$$(x_2 - 1)^2 \leq 2 - x_1$$
$$\boxed{(x_2 - 1)^2 \geq 1/2 + x_1}$$
$$x_1, x_2 \geq 0$$
$$x_1, x_2 \in \mathbb{Z}$$

The feasible region of the continuous relaxation is convex!!!

- IBM CPLEX can solve problems with convex quadratic constraints
- FICO XPRESS can solve nonlinear programs through linearization
- GUROBI can solve non-convex quadratic and bilinear programs

Complexity introduction

When analyzing an algorithm, we are interested in the amount of time and memory that it will take to solve it.

- To be safe this is usually answered in the **worst-case scenario**
- The discussion here will be mainly the time complexity of algorithms.
- We will use the "big-O" notation when given two functions $f : S \to \mathbb{R}_+$, $g : S \to \mathbb{R}_+$, where S is an unbounded subset of $\mathbb{R}_+$ we write that if there exists a positive real number M and $x_0 \in S$ such that $f(x) \leq Mg(x)$ for every $x > x_0$ then $f(x) = O(g(x))$
- For us S is going to be the set of instances or problems, and an *algorithm* is a procedure that will give a correct answer is a finite amount of time.
- An algorithm solves a problem in *polynomial time* if the function that measures its arithmetic operations $f : S \to \mathbb{R}_+$ is polynomially bounded by the function encoding the size of the problem $g : S \to \mathbb{R}_+$

Complexity introduction

- If there exists an algorithm that solves a problem in polynomial time, then that problem belongs to the complexity class P
  - For example LP belongs to P because the interior point algorithm solves it in poly-time

- A decision problem is one with answer "yes" or "no"
- The complexity class NP, non-deterministic polynomial, is the class of all decision problems where the "yes"-answer can be verified in poly-time

- If all the decision problems in NP can be reduced in poly-time to a problem Q, then Q is said to be NP-complete
  - "Is a (mixed-)integer linear set empty?" belongs to NP and is actually NP-complete

Complexity introduction

- A problem Q can be called NP-hard if all problems in NP can be reduced to Q in poly-time
    - Integer Programming is NP-hard
        - Since we can transform any NP problem into an integer program in poly-time, if there exists an algorithm to solve IP in poly-time, then we can solve any NP problem in poly-time: P=NP

- Integer programs with quadratic constraints are proved to be undecidable
    - Even after a long time without finding a solution, we cannot conclude none exists…
    - MINLP are **tough**!

Complexity introduction

- A problem is said to belong to the complexity class BPP, bounded-error probabilistic polynomial time, if there is an algorithm that solves it such that
  - It is allowed to flip coins and make random decisions
  - It is guaranteed to run in polynomial time
  - On any given run of the algorithm, it has a probability of at most 1/3 of giving the wrong answer, whether the answer is YES or NO.

- There exists another complexity class called BQP, bounded-error quantum polynomial time, which is the quantum analogue of BPP
  - We hope that some problems belong to BQP and not to BPP to observe Quantum Advantage
    - E.g., Integer factorization
The suspected relationship of BQP to other problem spaces

Take home message

Integer Programs lie at a very special intersection since they are:

- Interesting from an academic point of view
- Useful from a practical point of view
- Challenging from a computational point of view

We do not expect to observe Quantum Advantage by solving Integer Programs using Quantum Computers (but who knows right? Maybe P=BPP=BQP=NP)

We are still dealing with complicated problems that require answers, so we are going to try our best to solve them.

Welcome to Quantum Integer Programming!
